

Tracking the Internet's BGP Table

Geoff Huston

Telstra

November 2000

Methodology

- The BGP table monitor uses a router at the boundary of AS1221 which has a default-free BGP routing table
- Capture the output from “show ip bgp” every hour
- Perform analysis of the data
(and then discard the raw dump!)
- Update reports at
<http://www.telstra.net/ops/bgp>

Phases of Growth

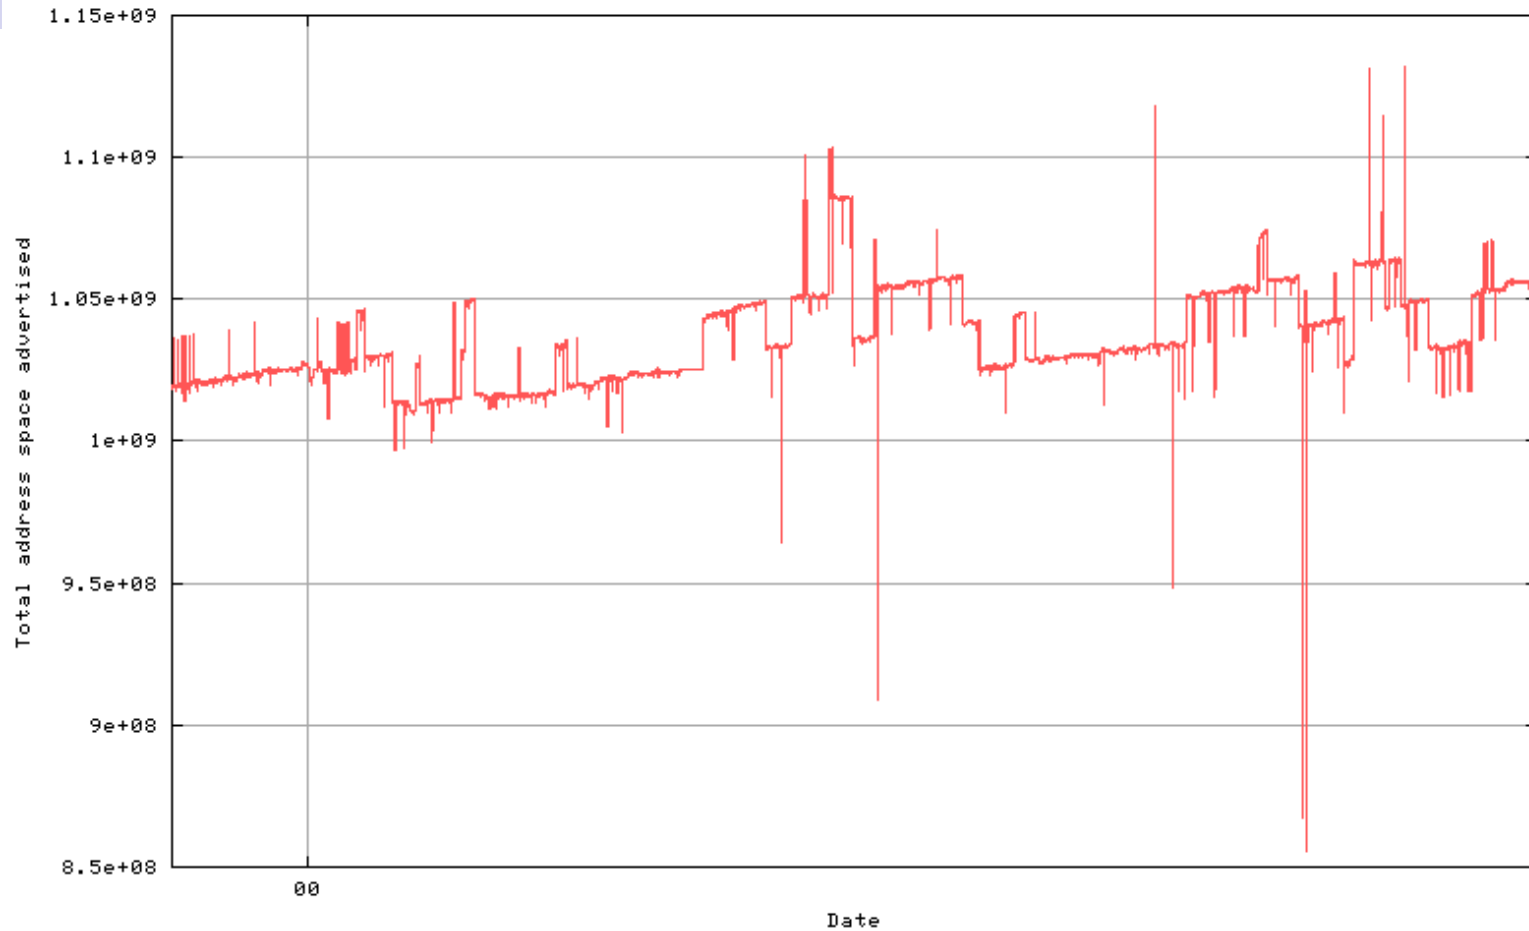

Growth Characteristics

- Short term route fluctuation is an absolute value (not a % of total routes) of 1,000 – 2,000 routes

Routed Address Space

Fluctuation is due to announcement / withdrawals of /8 prefixes
11 months of data does not provide clear longer growth characteristic

Routed Address Space (/8 Corrected)

Annual compound growth rate is 107% p.a.

Average size of a routing entry

The BGP routing table is growing at a faster rate than the rate of growth of announced address space

Number of AS's in the table

Exponential growth is evident in a longer term view of the AS deployment rate

AS Number Trend Models

Best fit model is an exponential model using 12 months of data

AS Number Use - Extrapolation

Number of distinct AS Paths

Observations for 99/00

- Linear rise in routed address space
5M x /32 / month
- Exponential rise in number of AS's
3.5% growth / month (151% / year)
- Exponential rise in number of route advertisements
3% growth / month (140% / year)
- Exponential rise in the number of routed addresses
0.6% growth / month (107% / year)

Multi-homing on the rise?

- Track rate of CIDR "holes" – currently 35% of all route advertisements are routing 'holes'

This graph tracks the number of address prefix advertisements which are part of an advertised larger address prefix

Prefix Growth – Aug 00 to Oct 00

/16	6553	->	6670	absolute growth =	117,	relative =	1.79%
/17	889	->	936	absolute growth =	47,	relative =	5.29%
/18	1763	->	1884	absolute growth =	121,	relative =	6.86%
/19	5704	->	5984	absolute growth =	280,	relative =	4.91%
/20	3423	->	3854	absolute growth =	431,	relative =	12.59%
/21	3621	->	3856	absolute growth =	235,	relative =	6.49%
/22	5415	->	5870	absolute growth =	455,	relative =	8.40%
/23	7298	->	7788	absolute growth =	490,	relative =	6.71%
/24	49169	->	52449	absolute growth =	3280,	relative =	6.67%
/25	208	->	436	absolute growth =	228,	relative =	109.62%
/26	334	->	606	absolute growth =	272,	relative =	81.44%
/27	469	->	667	absolute growth =	198,	relative =	42.22%
/28	357	->	452	absolute growth =	95,	relative =	26.61%
/29	579	->	764	absolute growth =	185,	relative =	31.95%
/30	746	->	1026	absolute growth =	280,	relative =	37.53%

The largest significant relative growth in recent times is /20, tracking the allocation policy change in the RIRs

While the absolute number is low, the largest relative growth is in /25 prefixes, and /25 to /30 represent the greatest area of prefix growth in relative terms

Tentative Conclusions

- BGP table size will continue to rise exponentially
- AS number deployment growth will exhaust 64K AS number space in 2005 if current growth trends continue
- Multi-homing at the edge of the Internet is on the increase
- The interconnectivity mesh is getting denser
 - The number of AS paths is increasing faster than the number of AS's

Tentative Conclusions (Cont)

- Inter-AS Traffic Engineering is being undertaken through routing discrete prefixes along different paths (the routing mallet!)
- RIR allocation policy (/19, /20) is driving the per-prefix length growth
- More noise (/25 and greater) in the table, but the absolute level of noise is low (so far)
